

Closure and Telicity across Categories*

(extended version)

Yoad Winter
Technion

July 2, 2006

1 Introduction

One of the fascinating aspects of telicity is its relations with non-verbal categories. Whether a given predicate is telic or atelic does not only depend on the verb, but can also be affected by the count/mass quantification in the NP object, by the lexical semantics of related adjectives, and by the prepositions that the predicate may contain. The latter two factors are in the focus of this paper. For example, the telicity of the deadjectival verb *straighten* and the complex verb phrase *jump into the water*, is related to the semantic structures of the adjective *straight* or the preposition *into*. A mathematical notion that is relevant to semantic domains across different categories is the notion of *closed intervals* – intervals that include their limit points. This paper studies the relations that closure properties of adjectives and prepositions bear to the (a)telicity properties of verb phrases. Following Rotstein and Winter (2004), closure of adjectival scales is treated as the defining distinction between two kinds of adjectives (e.g. *straight* vs. *bent*) that affects their behavior with *almost* modifiers. This leads to a conception of

*Special thanks to Carmen Rotstein, whose insights on deadjectival verbs prompted me to work on this topic. Thanks also to James Higginbotham, Malka Rappaport Hovav, Chris Kennedy, Stephen Wechsler and to the audiences at SALT 16 (Tokyo 2006) and at the workshop on scalar meaning (Chicago 2006). Chris Kennedy's invitation to the workshop in Chicago was a valuable encouragement for me while working on this paper. A short version of this paper is to appear in proceedings of SALT 16, and can be found at my webpage: <http://www.cs.technion.ac.il/~winter>

closure as the key source of ambiguity in verb phrases modified by *almost*, which is opposed to Dowty's (1979) characterization of such ambiguities in terms of telicity. The telic/atelic distinction between predicates is made explicit and is related to closure of adjectival scales and prepositional paths. This is done using a new notion of *weak downward monotonicity*, which refines the simple but crude *subinterval* (homogeneity) characterization of atelic predicates that was proposed in Bennett and Partee (2003).

Throughout this paper, when I say that a predicate is *telic*, I first of all mean that it does not support entailments from its progressive VP forms to corresponding non-progressive forms. Specifically – I will use (lack of) entailments from the past progressive to the past simple as a primary test for telicity. When such entailments are supported, the predicate is referred to as *atelic*. Thus, telic/atelic classifications are supported by contrastive pairs like the following.

- (1) Mary was drawing a circle $\not\Rightarrow$ Mary drew a circle (telic)
- (2) Mary was pushing a cart \Rightarrow Mary pushed a cart (atelic)

Many other syntactic and semantic effects have been classified as telicity phenomena. Especially, acceptability with *for/in* time adverbials is often used as another central test for a/telicity. However, since the correspondence between different tests for telicity is not complete, I will use entailment tests as in (1) and (2) as the primary test that is relevant for the phenomena treated in this paper.

Telicity factors interact with another cross-categorical phenomenon – constraints on the acceptability of the modifier *almost*. As exemplified in (3) below, *almost* appears with different syntactic categories, with various degrees of acceptability depending on the syntax and semantics of the item with which it combines.¹

- (3) a. *With NPs*:
almost every/no/thirteen/?some/?many/?few exam(s)
- b. *With adjectives*:
almost dry/?moist, almost clean/?dirty, almost ?wide/?narrow
- c. *With directional PPs*:
??almost toward the city, ?almost to the city

For the purposes of this paper, which concentrates on the relations between *almost* and telicity, a point of departure is an observation by Dowty (1979). Addressing

¹See Hitzenman (1992), Rapp and von Stechow (1999), Morzycki (2001), among others, for analyses of the behavior of *almost* with NPs; see Cruse (1986), Rotstein and Winter (2004) for its behavior with adjectives.

these relations, Dowty discusses two possible interpretations of sentences like the following, where *almost* combines with a telic predicate.

(4) Dan almost drew a circle.

One type of interpretation, which following Rapp and von Stechow (1999) I call the *scalar* (S) interpretation of *almost*, states that Dan started to draw a circle and got close to finishing it. Another kind of interpretation allows (4) to be true if Dan only got close to starting a drawing of a circle but didn't actually start. Rapp and von Stechow dub this the *counterfactual* (C) interpretation of *almost*. In many cases the S-interpretation of *almost* is not present. Consider for instance the following example, where *almost* modifies an atelic predicate.

(5) Dan almost pushed a cart.

In (5), the only possible interpretation of *almost* is the C-interpretation. An S-interpretation, claiming that Dan started and almost finished to push a cart, is hardly available. Dowty uses the availability of an S-interpretation for *almost* as a characteristic of telic predicates. Let us state this as in the following hypothesis.

(6) **Scalarity-telicity hypothesis:** A scalar interpretation of *almost* is available with a predicate P if and only if P is telic.

In view of the cross-categorical behavior of *almost* in (3), and the increasing body of work in recent years on scale structures of adjectives and path structures of prepositions, the value of Dowty's hypothesis for current research is in making another possible connection between such non-temporal ontologies and telicity.

This paper studies this connection further while taking Dowty's hypothesis as a starting point. My plan is as follows. In Section 2 I will argue that Dowty's hypothesis as stated in (6) is not completely adequate, and that the factor that affect S-interpretations is not telicity *per se*. Rather, I will claim that the same closure requirement that according to Rotstein and Winter (2004) determines acceptability of *almost* with adjectives should be used to describe the availability of its S-interpretation with verbs. Section 3 develops this idea by concentrating on the empirical relations between the scale structure of an adjective and the (a)telicity of the corresponding deadjectival verb. Section 4 formalizes the mapping from adjectives to deadjectival verbs and refines the *subinterval property* of atelic predicates that was proposed by Bennett and Partee (2003). With this novel characteristic of atelic predicates, which is called *weak downward monotonicity*, it is shown that an open/closed scale structure of an adjective directly leads to an a/telic temporal structure (respectively) of the corresponding verb. Section 5 shows that this

is no longer the case with respect to the more complex relations between the path structures of directional prepositions and the (a)telicity of verb phrases containing them. This dissociation between closure and telicity with directional PPs accounts for the counterexamples to Dowty's scalarity-telicity hypothesis.

2 *Almost* and prepositions: dissociating telicity from closure

Zwarts (2005) discusses some systematic differences between directional prepositions in terms of telicity. Using the *in/for* adverbial test, Zwarts addresses contrasts like the following.

- (7) a. Alex ran *toward* the park/*along* the river **in/for* a day.
 b. Alex jumped *into* the water/*ran onto* the platform/*walked out of* the hotel/*ran to* the park *in/*for* ten minutes.
 c. Alex ran *around* the lake/*across* the bridge/*through* the tunnel *in/for* one hour.

Zwarts' classification of prepositions is accordingly:

- (8) **Atelic:** *toward, along*
Telic: *to, into, onto, from, out of, off, away from, past, via*
Telic/atelic: *around, across, down, over, through, up*

This classification agrees with the following judgements on the validity of simple entailments from the past progressive to the past simple.

- (9) Dan was running *toward* the park \Rightarrow Dan ran toward the park
 Dan was running *along* the river \Rightarrow Dan ran along the river
 (10) Dan was running *to* the park $\not\Rightarrow$ Dan ran to the park
 Dan was jumping *into* the water $\not\Rightarrow$ Dan jumped into the water
 (11) Dan was running *around* the lake $\not\Rightarrow$ Dan ran around the lake
 Dan was running *across* the bridge $\not\Rightarrow$ Dan ran across the bridge
 Dan was running *through* the tunnel $\not\Rightarrow$ Dan ran through the tunnel

Note that we should expect that any telic reading of prepositions like *around*, *across* and *through* would block entailments as in (11) even if, as Zwarts proposes,

these prepositions are ambiguous between telic and atelic interpretations.²

The lack of entailment in (10) and (11) may lead us to expect, according to Dowty's hypothesis in (6), that the prepositions in these sentences support the S-interpretation of *almost*. However, there are some systematic contrasts that cast doubts on this expectation. Consider first the contrast between (12a) and (12b).

- (12) a. Dan almost walked around the lake. (C/?S)
b. Dan almost circled the lake. (C/S)

While it is easy for native speakers to accept (12b) as true if Dan started a circle around the lake but didn't finish it, judgements are less clear in (12a). The C-interpretation is possible in both (12a) and (12b), meaning that John was close to starting a path around the lake, but actually did not. A similar contrast appears between the following sentences.

- (13) a. Dan almost walked across the bridge. (C/?S)
b. Dan almost crossed the bridge. (C/S)

Infelicity of S-interpretations with telic prepositions also appears in the following examples.

- (14) Dan almost went to the park. (C/?S)
(15) Dan almost drove through the tunnel. (C/?S)

Quite in accordance with the marginality of these S-interpretations, English speakers I consulted had difficulties in accepting sentences like the following, where *almost* is prefixed to the PP itself.³

- (16) ?Dan ran almost around the lake/across the bridge/to the park/through the tunnel.

While judgements are sometimes insecure on such English sentences, there are other languages that allow us to draw a clear distinction between telic prepositions.

²Reasonably, when a sentence S_1 is ambiguous between readings A and B, where A entails a sentence S_2 but B does not, the entailment $S_1 \Rightarrow S_2$ will be invalid in natural language unless S_1 is somehow (e.g. contextually) disambiguated to exclude the B reading.

³Chris Kennedy (p.c.) points out that when directional prepositions are used in a locative manner, they may become much more acceptable with *almost*. Consider for instance sentences like *John is almost around the corner/across the bridge*. I will not address such examples here, but I believe the stative *be* predication may force a choice of the path's end-point, which derives a closed structure as the locative interpretation of *around* and *across*, and consequently licenses *almost* modification (see below).

Modern Hebrew is one language where a preposition parallel to English *until* also has spatial usages. The Hebrew preposition *@ad* (=‘until’) shows a clear contrast with the preposition *lella* (=‘to/to-the’) in terms of allowing modification using *kim@at* (=‘almost’). Consider the following Hebrew sentences.

- (17) a. ? dan rac kim@at la’agam.
 Dan ran almost to-the-lake
 ‘Dan ran almost to the lake’ (?S)
- b. dan rac kim@at @ad ha’agam.
 Dan ran almost until the-lake
 ‘Dan ran and almost reached the lake’ (S)

Hebrew speakers react to sentence (17a), with the preposition *le*, in a similar hesitation to English speakers who are confronted with sentences like (16). By contrast, sentence (17b) with the preposition *@ad* is clearly acceptable and, as evident from the translation, supports an S-interpretation for the modifier *kim@at* (=‘almost’). This is a bit surprising, since without *kim@at* the meanings of (17a) and (17b) may seem identical.

As can be expected, when *kim@at* appears before the VP, a noticeable distinction in the availability of the S-interpretation shows up between *le* and *@ad*:

- (18) a. dan kim@at rac la’agam.
 Dan almost ran to-the-lake
 ‘Dan almost ran to the lake’ (C/?S)
- b. dan kim@at rac @ad ha’agam.
 Dan almost ran until the-lake
 Ambiguous (C/S) –
 C: ‘Dan almost ran to the lake’
 S: ‘Dan ran and almost reached the lake’

A similar contrast can be observed in Dutch (Joost Zwarts, p.c.), with the prepositions *naar* (=‘to’) and *tot* (=‘until’):

- (19) a. Dan rende bijna naar het meer.
 Dan ran almost to the lake
 ‘Dan almost ran to the lake’ (C)
- b. Dan rende bijna tot (aan) het meer.
 Dan ran almost until the lake
 ‘Dan ran and almost reached the lake’ (S)

Why do pairs of telic predicates show contrasts in their tolerance toward the S-interpretation of *almost* modification, as opposed to what we might expect from Dowty’s hypothesis in (6)? My proposed answer essentially follows Rotstein and Winter’s intuition regarding the acceptability of *almost* modification. Rotstein and Winter propose that for *almost* modification of adjectives to be felicitous, the scale that is modified has to be *closed* – it should have a maximal point within it. Below I will extend this requirement for spatial and temporal-aspectual structures.⁴ I will argue that this closure condition by itself is sufficient for telicity, but it is not a necessary condition for telicity. Thus, telic structures may be open, and hence may disallow S-interpretations of *almost*.

Consider Figure 1. I propose that the path of spatial movement that we associate with prepositions like Hebrew *le*, Dutch *naar* or English *to* is open. By contrast, the corresponding path with *@ad/tot* (=‘until’) is minimally different but closed. Similarly, for the preposition *around* the path is proposed to be open, whereas the verb *to circle* is required to have a closed path. This difference is proposed as the factor that controls differences in acceptability with *almost*, but all the paths that are described in Figure 1 will be formally characterized as telic.

Figure 1: telic paths – open and closed

This line of explanation leaves us with some points that should be addressed. First, we should make sure that the distinction between closed and open adjectival scales carries over to the verbal domain. Important aspects of this mapping were already studied in Hay et al. (1999), but *almost* modification provides us with an additional test for closure and allows to define the mapping from scales to temporal structures more explicitly. Second, we should be able to formally derive our hypothesis that closed structures are inherently telic. Third, something similar should be done with the mapping from path structures of prepositions to

⁴For a similar parallelism between adjectives and verbs see Amaral (2006).

the temporal-aspectual domain where telicity is manifested. These issues are addressed in the following sections.

3 ‘Almost’, adjectives and the telicity of deadjectival verbs

This section first reviews Rotstein and Winter’s treatment of *almost* modification with adjectives of different scale structures. Then we move on to using this proposal in characterizing the (a)telicity of deadjectival verbs.

3.1 ‘Almost’ and the total/partial distinction

Previous works (Cruse (1986), Yoon (1996), Kennedy and McNally (2005), Rotstein and Winter (2004)), study pairs of adjectives like *dry-moist*, *clean-dirty*, and *healthy-sick*, which Yoon calls *total* and *partial* adjectives, respectively. Intuitively, one contrast between such adjectives is that partial adjectives indicate *some* amount of the relevant property (moisture, dirt, sickness etc.), whereas the total adjectives indicate *no* amount of this property. For instance, a dirty object has some degree of dirt, but it is not necessarily free of cleanliness. Conversely, a clean object is free of dirtiness, and it would be too weak to describe it as only having some degree of cleanliness. Some other pairs of adjectives where such intuitive distinctions hold are given in (20).

(20) **Total-partial adjectives:** *dry-moist, clean-dirty, healthy-sick, straight-bent/curved, smooth-rough, complete-incomplete, sharp-unsharp/blurred*

The distinction between total and partial adjectives was recently corroborated by Frazier et al. (2006) in a series of psycholinguistic experiments. Following Kennedy (2005), other pairs of antonymous adjectives will henceforth be referred to as *relative*.⁵ Some typical examples for relative adjectives follow.

(21) **Relative adjectives:** *long-short, expensive-cheap, wide-narrow, high-low, big-small, happy-unhappy* etc.

Cruse, and more recently Rotstein and Winter, study the different behavior of *almost* with total, partial and relative adjectives. In out-of-the-blue contexts, a

⁵Kennedy and McNally refer to total and partial adjectives as *maximum/minimum standard adjectives*. Kennedy (2005) further refers to the adjectives in these two subclasses as *absolute*, in distinction to the relative adjectives.

modified construction *almost A* is perfectly OK when *A* is a total adjective. But *almost A* is often marginal when *A* is partial or relative. Consider for instance the following examples.

- (22) almost dry/?moist, almost clean/?dirty, almost straight/?bent, almost smooth/?rough, almost complete/?incomplete
- (23) ?almost long/short, ?almost expensive/cheap, ?almost wide/narrow, ?almost big/small, ?almost fast/slow

Rotstein and Winter (henceforth R&W) point out that with some total-partial pairs of adjectives this contrast in acceptability is not so sharp. For instance, according to our intuitive criterion, the adjectives *healthy* and *sick* should be classified as a total-partial pair, but *almost sick* is not worse than *almost healthy*.⁶ R&W therefore suggest a simple semantic test that more easily identifies the *almost* contrast in total-partial pairs of adjectives. For instance, for the adjectives *healthy* and *sick* R&W note that if someone is *almost sick*, she is necessarily not *healthy*. By contrast, an *almost healthy* person can be (at least slightly) sick. This is illustrated below.

- (24) #She is almost sick but (still) healthy.
- (25) She is almost healthy but (still) sick.

Similar contrasts can be shown for the other adjectives in (20).

It was pointed out by Chris Kennedy (p.c. and in Kennedy 2005) that both partial adjectives and relative adjectives may allow *almost* in contexts that explicitly specify a standard. Some such examples are given below.

- (26) a. We need a rod that is bent in an angle of 90 degrees. Let's pick up that rod over there and bend it a little: it should be easy, as it's *almost bent* already.
- b. We consider a glass dirty and wash it as soon as there are five spots on it. This glass is now *almost dirty* – it has four spots on it.
- (27) a. We need a TALL basketball player – one whose height is at least 1.95 meters. But we cannot take John, who is 1.90 meters – he's just *almost tall*.
- b. The publisher considers a book long if it's 300 pages or more. This book is *almost long* – it's 298 pages.

⁶In fact, relatively to the number of Google hits for *sick* and *healthy*, the modified structure *almost sick* has significantly more hits than *almost healthy*.

To deal with these different behaviors of total, partial and relative adjectives, R&W propose three kinds of scale structures:

1. *Total scales*, in which the standard value is fixed on the zero degree and creates a *closed* interval of degrees associated with the adjective.
2. *Partial scales*, where the standard value is set by default to the zero degree and creates an *open* interval. This default can be overridden by context, which may then fix a standard at a positive degree and create a closed interval.
3. *Relative scales* are like partial scales, but they lack a default standard. Without a context, their standard can be anywhere and creates an open interval.

These three types of scales, with the possible contextual effects on them, are illustrated in Figure 2.⁷ R&W's semantics of *almost* assumes that this modifier requires that the interval *I* of degrees associated with an adjective *A* on the scale is closed from below. The interval associated with the adjectival phrase *almost A* is then assumed to be a (short) open interval adjacent to *I*. This requirement accounts for the facts observed above, and is illustrated in Figure 3. Throughout this paper I adopt this theoretical arrangement, which R&W discuss at length in their paper.

One thing to point out is that despite possible appearances, R&W's theoretical proposal does not impose a necessary semantic relation between partial and total adjectives. There may be total adjectives with no partial parallel, and vice versa. R&W's theoretical definitions of total scales and partial scales, unlike some of their empirical tests and assumptions about specific adjective pairs, are not based on the semantic behavior, nor on the existence, of antonymous pairs. For instance, in agreement with intuition, both adjectives in the pair *full-empty* can be classified as total adjectives with a zero standard and closed interval on two edges of a 'capacity' scale. No partial adjective should be related to either of these two adjectives. Further, the adjective *free* in the sense of 'without price' can be theoretically classified as total although it does not have a partial adjective related to it with a meaning like 'having some price'. The adjective *expensive*, which is of course semantically related to *free*, behaves like a relative adjective and not like a partial one – a standard value for *expensive* is by default unspecified, and when specified it is likely to be high above zero.

⁷See also Kennedy and McNally (2005), Hay et al. (1999), Kennedy (2005) for similar distinctions and further discussion.

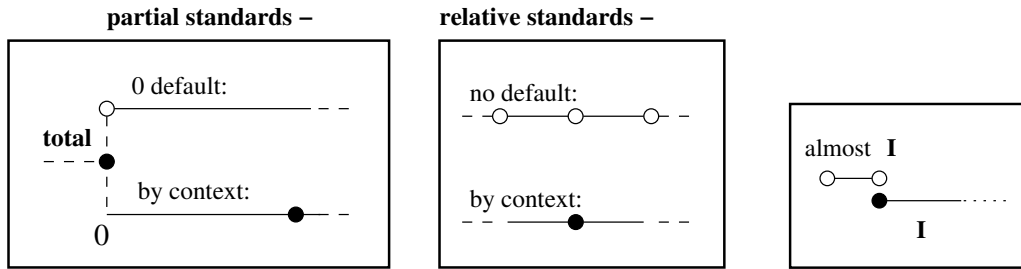

Figure 2: total, partial and relative scales

Figure 3: *almost*

3.2 The telicity of deadjectival verbs

One of the central topics in works on aspect and telicity has been to characterize the telicity of what Dowty (1979) calls *degree achievement* verbs: verbs like *grow*, *fall*, *increase*, *smoothen* etc.⁸ Verbs that are morphologically and semantically related to adjectives constitute an important subclass of the ‘degree achievement’ verbs. I henceforth refer to such verbs as *deadjectival* (DA) verbs. Some examples of DA verbs related to total, partial and relative adjectives are given below.

- (28) **Total-partial DA verbs:** *dry-moisten, clean-dirty, straighten-bend/curve, smoothen-roughen, sharpen-unsharpen/blur*
- (29) **Relative DA verbs:** *lengthen-shorten, widen-narrow, heighten-lower*

As many works point out,⁹ there are strong relations between (a)telicity of DA verbs and the classification of the corresponding adjectives. For instance, consider a sentence with a total DA verbs like *the towel was drying*. This sentence clearly does not entail that *the towel dried*: the drying process might have stopped in the middle. By contrast, the sentence *the towel was moistening* more likely entails that *the towel moistened*, at least with the ‘default’ understanding of *moist*. A similar contrast can be shown with the DA verbs *clean* and *dirty*. Consider first the following lack of entailment, which classifies the verb *clean* as telic.

- (30) John was cleaning the room $\not\Rightarrow$ John cleaned the room

With the verb *dirty*, as with most partial DA verbs, some care must be taken concerning their classification as atelic. Assume that we entered a room while John

⁸Many researchers consider the term *degree achievement* a misnomer, arguing that most verbs in this class are not what Vendler (1967) would classify as achievement predicates. In what follows I will not use this term.

⁹See Declerck (1979), Bertinetto and Squartini (1995), Hay (1998), Hay et al. (1999), Kearns (2005), among others.

was dirtying it. Can we conclude that John *dirtied* the room? In most contexts we probably can. But suppose that John had only managed to put just a little dirt in the room by the time we entered. Some contexts may require the room to become dirty to a high enough degree in order for a sentence like *John dirtied the room* to be true. In such contexts the entailment from the past progressive to the past simple may not go through. Still, the ‘default’ conclusion in most contexts would be that John dirtied the room. I will mark such default reasoning using the letter ‘D’ as in (31) below, in contrast to the clear lack of entailment in (30) above.

(31) John was dirtying the room \xrightarrow{D} John dirtied the room

A similar ‘default’ reasoning appears with relative DA verbs:

(32) a. Jane was lengthening the rope \xrightarrow{D} Jane lengthened the rope
 b. Jane was shortening the rope \xrightarrow{D} Jane shortened the rope

Hay et al. (1999) show that world knowledge or contextual factors may block such default conclusions with relative adjectives. Consider their examples below.

(33) The tailor was lengthening my pants $\not\Rightarrow$ The tailor lengthened my pants

(34) Kim was lowering the blind $\not\Rightarrow$ Kim lowered the blind

Clearly, *lengthen* in (33) requires that a certain length be attained, hence the failure of the inference. Likewise for (34). Something similar can be shown with partial DA verbs. Consider a computer program that runs over every pixel in a photo, and may change its color so to produce a ‘romantic’ blurred atmosphere in the picture. If we stop the program at the middle of the blurring process, it does not follow that the program blurred the photo. Obviously, there is a certain level of blurring that should be attained for this to happen. Thus we conclude that despite the out-of-the-blue atelicity of partial DA verbs like *blur* or *unsharpen*, they do not support atelicity entailments when a non-zero standard is assumed as in the following example.

(35) The program was blurring/unsharpening the photo $\not\Rightarrow$ The program blurred/unsharpened the photo

We see that the atelicity of partial and relative DA verbs is only a tendency, which is sensitive to contextual factors. By contrast, as far as I could check it this is not the case with the telicity of total DA verbs. I find it hard to think of contexts that allow to conclude that *the towel dried* when all we know is that *the towel was drying*. Similarly for other total DA verbs: all of them seem to behave

in this respect like typical telic predicates.¹⁰ We summarize this in the following generalization.

- (G1) Total DA verbs are uniformly telic. Partial and relative DA verbs are atelic by default, but contextual factors can make them telic.

From the literature on DA verbs we can also extract a related generalization concerning the relations between the DA verb and the positive form of the corresponding adjective. Consider the following sentences.

- (36) a. Mary has dried the towel/cleaned the room/straightened the rope/sharpened the photo.
b. Mary has moistened the towel/dirtied the room/bent the rope/unsharpened the photo.
- (37) a. Jane has lengthened the rope/widened the gap/heightened the book.
b. Jane has shortened the rope/narrowed the gap/lowered the book.

From the respective examples in both (36a) and (36b) we can conclude that the towel is dry/moist, that the room is clean/dirty, etc. By contrast, from (37a) and (37b) we cannot conclude that the rope is long/short, that the gap is wide/narrow etc. Thus, with both total and partial DA verbs, the present perfect tense entails the positive form of the adjective. However, with relative DA verbs this is not the case.

These claims may seem to be in opposition to certain claims that were made in the literature. For instance, Hay et al. (1999) mention the example *I straightened the rope, but not completely*, and indicate that it does not entail that the rope became straight. However, this lack of entailment relies on the adverb *completely*. Without it, a statement like *I straightened the rope, but it isn't straight* is odd, if not strictly contradictory.¹¹ Declerck (1979) mentions another example:

- (38) The corn dried in the fields for two days, but it was not completely dry when a cloudburst soaked it again.

¹⁰Note, however, that many total DA verbs allow modification by *for* adverbials, as in Declerck's (1979) example: *the corn dried for three days*. However, as Dowty (1979) points out, *for* adverbials can turn a (telic) accomplishment into an (atelic) activity, so they cannot always be relied on as a test for atelicity. See more on other telicity tests for such verbs in Hay et al. (1999), Kearns (2005).

¹¹The contrast follows from R&W's distinction between *straight(en)* and *completely straight(en)*, which I will not discuss here.

The felicity of this example relies not only on the presence of the adverb *completely*, but also, as mentioned above (see note 10), it involves the *for* adverbial, which often turns (telic) accomplishments into (atelic) activities. To see the confounding effect of these two factors consider the following example as opposed to (38).

- (39) #The corn dried in the fields, but it was not dry when a cloudburst soaked it again.

The contrast between (38) and (39) suggests that total DA verbs entail the positive form of the respective adjective, and only additional factors may block such entailments. As far as I could check, no contextual factors can block such entailments, and this is true also for partial DA verbs. As for the relative DA verbs, even in cases like Hay et al.'s (33) and (34), where the standard that is assumed forces the relative DA verb to behave in a telic manner, the positive form of the adjective is not entailed. Consider the following lack of entailments.

- (40) The tailor has lengthened my pants \nrightarrow My pants are long
(41) Kim has lowered the blind \nrightarrow The blind is low

Concluding, I suggest the following generalization.

- (G2) Total DA verbs and partial DA verbs entail the positive form of the respective adjective, whereas relative DA verbs do not.

Let us now move on to the account of generalizations (G1) and (G2).

4 The A-V mapping and telicity

To account for the facts that are summarized under (G1) and (G2) we need to have a mechanism that systematically relates the meaning of DA verbs to the meaning of the corresponding adjectives. Further, to account for generalization (G1) we have to use a formal characteristic of telicity that distinguishes between the three classes of DA verbs in accordance with their temporal-aspectual behavior. These two problems are the subject of this section.

4.1 The A-V mapping

We will assume that verbs have a temporal interval argument that is responsible for describing their temporal behavior.¹² DA verbs describe a process that is related to a degree change of one of their arguments – subject in intransitive sentences (e.g. *the gap widened*), object in most transitive sentences (e.g. *the workers widened the road*). We assume that a DA verb holds at the temporal intervals I that satisfy the following two properties, in relation to the relevant argument:

- (42) *Progress* – the degree of the verb’s argument on the scale of the corresponding adjective increases during the interval I .
- (43) *Culmination* – at the end of the interval I , the degree attained is within the set of degrees associated with the adjective, if such a set is specified by a given standard value.

Consider for example the total DA verb *straighten*. ‘Progress’ means that at any temporal interval I , an entity x straightens at I only if at the end of I the entity x is straighter than what it was at the beginning of I . ‘Culmination’ means that at the end of I the entity x is within the set of degrees associated with *straight*, i.e. the sentence *x is straight* is true. By our definition of total scales this means that a *straightening* process entails moving from a positive degree of curvedness to zero curvedness. For a partial DA verb like *bend*, progress and culmination entail that without contextual information, a *bending* process involves moving from any degree of curvedness to a higher and positive degree of curvedness. For a relative DA verb like *widen*, in the absence of contextual information a *widening* process only requires progress (i.e. becoming wider). This is because culmination would require there to be a standard value associated with the adjective *wide*, and no such standard is given by default. These three different kinds of process that we assume are illustrated in Figure 4.

It is easy to see how these assumptions account for generalization (G2) in the absence of contextual knowledge: total and partial adjectives have a default standard, hence culmination is responsible for the entailment from the DA verb to the positive form of the adjective. Conversely for relative adjectives: the lack of such entailments is expected by the nullified culmination requirement. The question of partial and relative DA verbs in contexts that make a standard value

¹²We can of course translate this assumption to frameworks that assume an event argument for the verb, by using the running time of the event as an indirect interval argument.

Figure 4: total, partial and relative DA verbs – solid (dashed) lines describe processes which are (are not, respectively) in the DA verb’s denotation

explicit will not be discussed in this paper.¹³

Let us now formally define the A-V mapping using the progress and culmination requirements. To do that, we first assume that an adjective specifies degrees of entities over instants of time. Formally, this means that an adjective A specifies a *temporal dimension function* dim_A that for each entity x determines x ’s degree on the corresponding scale at any instant. Further, when a standard value is given, the adjective also characterizes which entities are associated with its positive form. This is done by deriving an open/closed set of degrees on the scale from the given standard value.

Definition 1 (adjectival information) Let $\langle S, \leq_s \rangle$ be a **scale** – a partially ordered set of **degrees**. An adjective that is associated with $\langle S, \leq_s \rangle$ specifies a function dim_A and (optionally) a set of degrees $D_A \subseteq S$ such that:

$dim_A : (E \times T) \rightarrow S$ is a **temporal dimension function** from entities in E and temporal instants in T to degrees in S ;

$d \in S$ is an optional **standard value** in S , and $D_A = \{d' \in S : d \leq_s d'\}$ (an interval closed from below) or $D_A = \{d' \in S : d <_s d'\}$ (an interval open from below).

The intervals associated with a DA verb corresponding to an adjective A are specified in the following definition using a function V_A from entities in E to sets of temporal intervals over T .

¹³In such contexts, the proposal in this paper expects an entailment from the DA verb to the positive form of the relative adjective, if the standard value remains constant through the entailment. But (40) and (41) show that this does not have to be the case. I will not get here into the analysis of such effects, which may result from a change of standard value between the premise and conclusion of the entailment.

Definition 2 (A-V mapping) For an adjective A , let dim_A be a temporal dimension function over a scale $\langle S, \leq_S \rangle$, and let $D_A \subseteq S$ be an optionally given set of degrees in S . Then the function V_A maps every entity $x \in E$ to the set of intervals I over T , s.t. the following two conditions hold:

Progress: $dim_A(x, inf(I)) <_S dim_A(x, sup(I))$;

Culmination: If D_A is given, then $dim_A(x, sup(I)) \in D_A$.

For any adjective A , the function V_A thus describes a binary relation between entities and temporal intervals, so that for every entity x , $V_A(x)$ is the set of intervals at which the DA verb corresponding to A holds of x . For simplicity, we only treat here intransitive verbs, but the extension to verbs with more than one syntactic argument is straightforward. Standardly, the functions sup and inf correspond to the supremum and infimum functions, which here are necessary in order to deal with possibly open intervals.

To exemplify the application of this definition, consider the proposed set of intervals corresponding to the partial DA verb *bend*, where S_B is the scale of ‘bendedness’.

$$(44) \quad \begin{aligned} \mathbf{bend}'(x) &= V_{bent}(x) \\ &= \{I : dim_{bent}(x, inf(I)) <_{S_B} dim_{bent}(x, sup(I)) \wedge \\ &\quad dim_{bent}(x, sup(I)) \in D_{bent}\} \end{aligned}$$

By our assumption on partial scales, $D_{bent} = \{d \in S_B : d >_{S_B} 0\}$. Hence:

$$= \{I : dim_{bent}(x, inf(I)) <_{S_B} dim_{bent}(x, sup(I)) \wedge \\ dim_{bent}(x, sup(I)) >_{S_B} 0\}.$$

For the total DA verb *straighten*, we get the following set of intervals, where S_S is the scale of ‘straightness’:

$$(45) \quad \begin{aligned} \mathbf{straighten}'(x) &= V_{strt}(x) \\ &= \{I : dim_{strt}(x, inf(I)) <_{S_S} dim_{strt}(x, sup(I)) \wedge \\ &\quad dim_{strt}(x, sup(I)) \in D_{strt}\} \end{aligned}$$

By our assumption on total scales $D_{strt} = \{d \in S_S : d \geq_{S_S} 0\}$. Hence:

$$= \{I : dim_{strt}(x, inf(I)) <_{S_S} dim_{strt}(x, sup(I)) \wedge \\ dim_{strt}(x, sup(I)) \geq_{S_S} 0\}$$

We of course assume $S_S = S_B$ and $dim_{strt}(x, t) = dim_{bent}(x, t)$ for every instant t . This is because *straight* and *bent* pertain to the same degrees and give rise to inverse comparative order relations: $x \leq_{S_S} y$ iff $y \leq_{S_B} x$. Thus, we have:

$$= \{I : \dim_{bent}(x, \inf(I)) >_{S_B} \dim_{bent}(x, \sup(I)) \wedge \wedge \\ \dim_{bent}(x, \sup(I)) \leq_{S_B} 0\}.$$

The set of intervals for relative DA verbs like *lengthen* or *shorten*, with the relative scales S_{LG} and S_{ST} , are simpler due to the lack of the culmination requirement:

$$(46) \quad \mathbf{lengthen}'(x) = V_{long}(x) \\ = \{I : \dim_{long}(x, \inf(I)) <_{S_{LG}} \dim_{long}(x, \sup(I))\}$$

$$(47) \quad \mathbf{shorten}'(x) = V_{short}(x) \\ = \{I : \dim_{short}(x, \inf(I)) <_{S_{ST}} \dim_{short}(x, \sup(I))\} \\ = \{I : \dim_{long}(x, \inf(I)) >_{S_{LG}} \dim_{long}(x, \sup(I))\}$$

After defining the sets of intervals for various DA verbs using the scale structure of the corresponding adjectives, we can now get back to the problem of (a)telicity, and use these definitions in its treatment.

4.2 Weak downward monotonicity and (a)telicity

Bennett and Partee (2003) provide a well-known definition of atelicity using what they call the *subinterval property*. Let \mathcal{I} is the set of (open and closed) intervals over some partially ordered set. A set $\mathcal{J} \subseteq \mathcal{I}$ has the subinterval property iff it is downward monotone in \mathcal{I} . That is, for all $I, I' \in \mathcal{I}$ s.t. $I' \subseteq I \in \mathcal{J} : I' \in \mathcal{J}$.

Bennett and Partee propose the subinterval property as the defining property of atelic predicates, and further assume that any predicate that lacks it is by definition telic. This proposal follows the intuition that atelic predicates like *walk* are ‘homogeneous’: if John walked between 2pm and 4pm, he obviously must have walked at many subintervals of the [2:00,4:00] interval, certainly in big enough subintervals. For instance, he must have walked between 2:01 and 3:59. With telic predicates, no subinterval property has to hold. For instance, if John drew a circle between 2pm and 4pm, it is not necessary that there was any subinterval of [2:00,4:00] where he completed a circle, hence the lack of subinterval property.

A well-known problem with the subinterval property is that it puts too strong a restriction on atelic predicates. To be sure, if John walked between 2pm and 4pm, it does not necessarily follow that he walked between 2:38 and 2:39. On that specific moment he might have stopped for a short rest without violating the truth of the premise. This problem for the subinterval definition of atelicity is reminiscent of the much discussed ‘Sorites paradox’ for the meaning of adjectives. For instance, supposing that a digital camera that costs \$4,000 is considered expensive,

it reasonably follows that also a digital camera that costs \$3,999 is expensive. But it does not follow that a digital camera that costs \$39 is expensive.¹⁴

Thus, with both atelic predicates and adjectives that trigger the Sorites problem, some sort of downward monotonicity is required, but we cannot use the monotonic inference pattern ‘all the way down’. I propose that what characterizes both situations is a notion that I call *weak downward monotonicity* ($WM\downarrow$): both the intervals associated with atelic predicates and the degrees associated with Sorites-sensitive adjectives allow *approximation* while going downward. Thus, from sentence (48a) we cannot draw conclusions about all subintervals of [2:00,4:00], but we can conclude the statement in (48b).

- (48) a. John walked between 2pm and 4pm.
 b. \Rightarrow There is a proper subinterval I' of [2:00,4:00] such that John walked in all the subintervals I'' that satisfy $I' \subsetneq I'' \subseteq [2:00,4:00]$.

We can say that the interval I' approximates from below the interval [2:00,4:00] of John’s walking. How much smaller than [2:00,4:00] intervals like I' are required to be is determined by context, but the requirement about at least one such I' is context-independent. This conception is inspired by the informal discussion of Borik (2002), which I believe reflects a similar intuition. A typical situation that exemplifies this weak monotonicity requirement of atelic predicates is illustrated in Figure 5.

Figure 5: weak downward monotonicity with *walk*

I tentatively suggest that a similar approach can be used to deal with the Sorites problem in general. Thus, sentence (49a) does not entail that any specific price below \$4,000 is expensive for a digital camera; it only makes the requirement stated in (49b).

¹⁴Kennedy (2005) is a recent linguistic discussion of the Sorites problem that is especially relevant for our discussion, since Kennedy claims that only relative adjectives, but not partial or total adjectives, show the Sorites paradox.

- (49) a. A digital camera that costs \$4,000 is expensive.
 b. \Rightarrow There is a price p' lower than \$4,000 such that for all prices p'' s.t. $p' < p'' \leq \$4,000$: a camera that costs p'' is expensive.

How much lower than \$4,000 the price p' in (49b) is required to be is again determined by context.

Let us now formally define the notion of weak downward monotonicity. In this definition we say that an interval I' is *properly within* I iff $\text{sup}(I') < \text{sup}(I)$ and $\text{inf}(I') > \text{inf}(I)$.

Definition 3 (weak downward monotonicity) *Let \mathcal{I} be the (open and closed) intervals over some partially ordered set. A set $\mathcal{J} \subseteq \mathcal{I}$ is weakly downward monotone ($WM\downarrow$) iff for every $I \in \mathcal{J}$ there is $I' \in \mathcal{I}$ s.t. I' is properly within I , and for every $I'' \in \mathcal{I}$: if $I' \subsetneq I'' \subseteq I$ then $I'' \in \mathcal{J}$.*

I propose the following hypothesis:

- (50) *For any atelic predicate P , the set of intervals associated with P is $WM\downarrow$.*

Thus, weak downward monotonicity is a necessary condition for atelicity. Hence, its absence is a sufficient condition for telicity. Weak monotonicity is only used here as a necessary condition for atelicity because predicates that pass standard tests for atelicity normally have stronger monotonicity requirements than weak downward monotonicity. For instance, in sentence (48), we would probably consider it an unnatural situation if the denotation of *walk* only contained intervals that approximate the two-hour interval [2:00,4:00], but no shorter intervals of walking. How to strengthen the hypothesis in (50) into a full definition of atelic denotations is something that I will not attempt to do here, especially since the hypothesis in (50) is sufficient for the purposes of this paper.

Using the proposed A-V mapping, we can apply hypothesis (50) to formally derive the (a)telicity of DA verbs. Note first that the A-V mapping makes a necessary requirement from DA verbs. However, this requirement itself does not yet guarantee that relative and partial DA verbs are atelic. This is as it should be, since we have already seen (cf. sentences (33), (34), (35)) that such DA verbs can show a telic behavior when context or world knowledge add a standard value that creates a closed interval. Furthermore, DA verbs like *straighten*, *bend* or *widen* do not necessarily reflect a gradual process in terms of the degree change on the adjective scale. And lack of graduality may block atelicity, as well as weak downward monotonicity. For instance, as Stephen Wechsler (p.c.) points out, when a road is widened very often no progress in its width happens before the final stages

of the widening process. In such scenarios, the transitive verb *widen* may fail the progressive test for atelicity: if the workers are widening the road, it does not follow that they have widened it, even not a little.

We conclude that for a DA verb to satisfy weak downward monotonicity, and show atelic behavior, the intervals that it contains should be part of a gradual process along the scale, as described by the corresponding temporal dimension function. This notion of graduality is standard continuity and upward monotonicity of the temporal dimension function in its temporal argument, defined as follows.

Definition 4 (graduality along a scale) *Let dim_A be a temporal dimension function over a scale $\langle S, \leq_s \rangle$ for entities E and temporal instants T . For $x \in E$, the function dim_A is said to be **gradual along S** in an interval $I \subseteq T$ iff $\lambda t. dim_A(x, t)$ is upward monotonic in I , and for every t in the closure of I ($= I \cup \{inf(I)\} \cup \{sup(I)\}$), for every $\epsilon > 0$:*

*If $t > inf(I)$ then there is $t' \in I$ s.t. $t' < t$ and $0 \leq dim_A(x, t) - dim_A(x, t') < \epsilon$;
If $t < sup(I)$ then there is $t' \in I$ s.t. $t < t'$ and $0 \leq dim_A(x, t') - dim_A(x, t) < \epsilon$.*

Intuitively, a temporal dimension function dim_A describes a gradual process along the corresponding scale in an interval I if dim_A describes progress along the scale in I (i.e. dim_A is upward monotonic in I), and this progress in I is continuous.

When a temporal dimension function describes a gradual process, our A-V mapping captures the parallelism between open/closed scales and $WM\downarrow/\neg WM\downarrow$ sets of intervals, respectively. The following proposition establishes weak downward monotonicity of the DA verbs corresponding to partial adjectives, whose scales are open, and to relative adjectives, where no standard value is given.

Proposition 1 *Let $dim_A, \langle S, \leq_s \rangle, D_A \subseteq S$ and V_A be as in definition 2. For some entity $x \in E$ assume that dim_A is gradual along S in every $I \in V_A(x)$. If $D_A \subseteq S$ is given and open from below, or if D_A is not given, then $V_A(x)$ is $WM\downarrow$.*

The intuitive reason for this result is that graduality guarantees that progress in an interval I entails progress in subintervals I' that approximate it. If D_A is open from below and I further attains a degree in D_A , the degree attained at the supremum of I must be greater than the standard value. Graduality guarantees that this culmination at I leads to culmination at intervals that approximate I 's supremum. Both progress/culmination at I thus lead to progress/culmination at intervals that approximate I from below, hence the weak downward monotonicity of V_A . This is illustrated in Figure 4 above for partial and relative scales. A more formal proof follows.

Proof: Let I be in $V_A(x)$, and let us denote:

$\inf(I) = t_1$, $\sup(I) = t_2$, $\dim_A(x, t_1) = d_1$, $\dim_A(x, t_2) = d_2$.

By progress in $V_A(x)$, we have $d_1 < d_2$. Let $\epsilon > 0$ be s.t. $\epsilon < (d_2 - d_1)/2$.

By graduality of \dim_A in I , there are $t_1', t_2' \in I$ s.t. $t_1 < t_1' < t_2' < t_2$,

$0 \leq \dim_A(x, t_1') - d_1 < \epsilon$ and $0 \leq d_2 - \dim_A(x, t_2') < \epsilon$. Let us denote

$d_1' = \dim_A(x, t_1')$ and $d_2' = \dim_A(x, t_2')$. By choice of ϵ we conclude that

$d_1' < d_2'$, and hence \dim_A satisfies progress for x over the interval $I'_1 \stackrel{\text{def}}{=} [t_1', t_2']$,

which is properly within I . By upward monotonicity of \dim_A in I , the same holds for every interval I'' s.t. $I'_1 \subsetneq I'' \subseteq I$.

If D_A is not given, then by definition of V_A this entails that any such I'' is in $V_A(x)$, hence $V_A(x)$ is $WM\downarrow$.

Let us assume now that D_A is given and open from below. By culmination, d_2 is in D_A . Because D_A is open from below, we have $d = \inf(D_A) < d_2$ (d is the standard value for D_A). Let $\epsilon > 0$ satisfy $\epsilon < d_2 - d$. By graduality of \dim_A in I there is $t_2'' \in I$ s.t. $t_2'' < t_2$ and $0 \leq d_2 - \dim_A(x, t_2'') < \epsilon$. Hence, $\dim_A(x, t_2'') > d$, or $\dim_A(x, t_2'') \in D_A$.

We have seen that \dim_A satisfies progress for x over $[t_1', t_2']$ and culmination for x over $[t_1', t_2'']$. By upward monotonicity of \dim_A over I , we conclude that \dim_A

satisfies progress and culmination for x over the interval $I' \stackrel{\text{def}}{=} [t_1', \max(t_2', t_2'')]$.

By upward monotonicity of \dim_A in I , the same holds for every interval I'' s.t. $I' \subsetneq I'' \subseteq I$, and by definition of $V_A(x)$ we have $I'' \in V_A(x)$. Hence $V_A(x)$ is $WM\downarrow$.

The following proposition shows that weak downward monotonicity is not guaranteed for total DA verbs, where the respective scale is closed from below.

Proposition 2 Let $\langle S, \leq_S \rangle$ and $D_A \subseteq S$ be a scale and a set of values on it as in definition 2, where D_A is closed from below. Then there is a temporal dimension function \dim_A and an entity $x \in E$ s.t. \dim_A is gradual for x along S for every $I \in V_A(x)$, and $V_A(x)$ is not $WM\downarrow$.

Intuitively, the reason for this result is that, when D_A is closed from below and an interval I culminates at the *infimum* of D_A , even a gradual temporal dimension function cannot guarantee that any subinterval of I would culminate within D_A . Hence V_A is not $WM\downarrow$. This is illustrated in Figure 4 above for total scales.

Proposition 2 is weaker than what might be expected. It only guarantees telicity of total DA verbs in some cases, but not in all cases. This is sufficient at least in what concerns the main telicity criterion that is used in this paper: the lack of

entailment involving the progressive. For the entailment to fail, it is enough to show one situation where the set of intervals associated with the verb is classified as telic (or $\neg WM\downarrow$). There are two reasons why the set of intervals that is associated with a total DA verb may not exhibit telicity. First, according to our definition, it may well happen that the temporal dimension function is gradual but not *properly* upward monotone. For instance, the children may clean the room gradually while at certain intervals within the process the cleanliness of the room remains constant. We have not excluded a situation where the process of cleaning the room ends with an interval with no progress in cleanliness. This may cause weak downward monotonicity. A second possible reason for weak monotonicity with total DA verbs, is that R&W allow total adjectives like *clean* to be associated with negative degrees, in addition to the zero degree. R&W do that in order to be able to compare in terms of cleanliness also entities that are categorized as *clean*. For instance, two tables can be called *clean* even though one of them is *very clean* or *completely clean* and the other one is not. If more than just the zero degree is allowed for total adjectives, a cleaning process may turn a clean object into a very clean object, while still satisfying both progress and culmination. This makes the process weakly downward monotone. In this paper I will not try to rule out such situations of atelic sets of intervals for total DA verbs, and I see no reason to consider them illicit. The distinction between total DA verbs and partial/relative DA verbs in terms of telicity is captured by the current assumptions above, and we do not need to strengthen these assumptions without further motivation.

5 Back to path structures

In the previous section we have seen a parallelism between the closure of a scale and the weak downward monotonicity of the corresponding DA verb. However, the starting point of this paper was that the behavior of spatial prepositions with *almost* suggests that the parallelism between closure and telicity is not complete. This section briefly proposes an account of the opposition between the case of DA verbs and the case of directional prepositions. Reconsider the contrast between directional prepositions like *to* in English, and prepositions like *@ad* in Hebrew or *tot* in Dutch. To account for the contrasts in acceptability of *almost* modification, I proposed that the former preposition describes an open path whereas the latter two prepositions describe closed paths. Both kinds of preposition give rise to *telic* predicates when they combine with verbs. To see why, we need to focus on the semantics of verb phrases with such directional prepositions.

Let us refer by TO to prepositions of the *to* variety and by TOT to prepositions of the *@adltot* variety. Following many works (see e.g. Zwarts and Winter (2000) and the references therein), we assume that the denotation of a directional preposition is a collection of spatial *paths*: functions from intervals to *locations* in space. Let \mathcal{I} be the set of intervals and L be the set of locations, described using our favorite spatial ontology. The denotations of PPs like TO *the park* or TOT *the park* are collections of functions whose domains are (possibly different) intervals in \mathcal{I} and their ranges are L . Specifically, we assume:

$$\text{TO}_{\mathbf{p}'} = \bigcup_{I \in \mathcal{I}} \{f \in L^I : I \text{ is open from above and } f(\text{sup}(I)) = \text{loc}(\mathbf{p}')\}$$

$$\text{TOT}_{\mathbf{p}'} = \bigcup_{I \in \mathcal{I}} \{f \in L^I : I \text{ is closed from above and } f(\text{max}(I)) = \text{loc}(\mathbf{p}')\}$$

Here we assume that $\text{loc}(\mathbf{p}')$ is the (static) location of the park. The difference between the two collections of paths is that in the first case, the path functions are from open intervals whereas in the second case these are closed intervals. In both cases, at the supremum of the interval the location attained by the path is the location of the park. In the case of TOT, this supremum is moreover a maximum.

Verb phrases like *ran* or *ran TO/TOT the park* are associated with a set of intervals for each entity argument. The latter modified VPs are derived from the verb (or simple VP) *ran* by first looking at the location of the subject in each instant. Let us use a *temporal location function* for this purpose, such that $\text{loc}(x, t) \in L$ is the location of an entity $x \in E$ at an instant $t \in T$. To form the denotation of a VP of the form [V PP], those intervals for which the *loc* function describes a path in the denotation of PP are intersected with the intervals of V. Formally:

$$(51) \quad \llbracket \text{V PP} \rrbracket(x) \stackrel{\text{def}}{=} \llbracket \text{V} \rrbracket(x) \cap \{I \in \mathcal{I} : (\lambda t_{t \in I}. \text{loc}(x, t)) \in \llbracket \text{PP} \rrbracket\}$$

$\llbracket \text{V PP} \rrbracket$ and $\llbracket \text{V} \rrbracket$ are here relations between entities and intervals. We get:

$$(52) \quad \llbracket \text{run TO the park} \rrbracket(x) = \mathbf{run}'(x) \cap \{I \in \mathcal{I} : (\lambda t_{t \in I}. \text{loc}(x, t)) \in \text{TO}_{\mathbf{p}'}\}$$

In words: the intervals where x ran TO the park are those intervals where x ran, and where x 's change of location created a path TO *the park*. By assumption on TO, (52) is equal to:

$$\mathbf{run}'(x) \cap \{I \in \mathcal{I} : I \text{ is open from above and } \text{loc}(x, \text{sup}(I)) = \text{loc}(\mathbf{p}')\}.$$

In words: I is an interval at which x ran TO the park if I is open from above and at I 's upper limit x was at the park. Further, consider TOT:

$$(53) \quad \llbracket \text{run TOT the park} \rrbracket(x) = \mathbf{run}'(x) \cap \{I \in \mathcal{I} : (\lambda t_{t \in I}. \text{loc}(x, t)) \in \text{TOT}_{\mathbf{p}'}\} \\ = \mathbf{run}'(x) \cap \{I \in \mathcal{I} : I \text{ is closed from above and } \text{loc}(x, \text{max}(I)) = \text{loc}(\mathbf{p}')\}$$

In words: I is an interval at which x ran TOT the park if I is closed from above and at the end of I , x was at the park.

The difference we argued for concerning the acceptability of *almost* modification of (52) (marginal) and (53) (OK), follows from the open intervals in (52) as opposed to the closed intervals in (53). Crucially, however, both sets of intervals are not necessarily $WM\downarrow$. With respect to both TO and TOT, intervals at the end of which x was at the park do not necessarily contain any smaller interval at the end of which x was at the park. In particular this is true when x 's motion, described using the temporal location function, is 'smooth' or 'gradual' in a sense parallel to the definition of graduality of temporal dimension functions.

We conclude that open path structures, as opposed to open scalar structures, do not necessarily involve an atelic temporal-aspectual behavior. Whether an open structure creates atelicity depends on the mapping from this structure to the temporal-aspectual structure of verb. Specifically, the A-V mapping derives atelic ($WM\downarrow$) structures from open structures, whereas the P-V mapping does not. This contrast is illustrated in Figure 6, where $I'_1 \subseteq I$ illustrates weak downward monotonicity with an open scale of the partial DA verb *bend*, but $I'_2 \subseteq I$ illustrates lack of weak downward monotonicity with the open path of the TO preposition.

Figure 6: weak downward monotonicity of *bend*, as opposed to *walk in the park* – in both cases I is associated with the predicate; however I'_1 is associated with *bend* whereas I'_2 is not associated with *walk to the park*

6 Summary

Let me review the main points of this paper. First, following Rotstein and Winter it was argued that closure is the key ingredient in allowing *almost* modification. This was claimed to be true also for the scalar interpretation of *almost* with

verb phrases, modifying Dowty's characterization of this interpretation in terms of telicity. After establishing formal connections between adjectival scale structures and verbal temporal structures, in agreement with Hay et al.'s observations, closure of a scale was shown to guarantee telicity of the corresponding deadjectival verb. With such verbs, the symmetry also carries over to the relation between open scales and atelicity. However, this was claimed not to be the case with verb phrases formed using some directional prepositions. In such cases, the verb phrase can be telic whereas scalar modification by *almost* fails, which indicates an open path structure. Throughout this paper, I used weak downward monotonicity as the relevant characteristic of atelicity, at least in what concerns the entailment from the progressive to perfective tenses. More work needs to be done on the relation between this new characterization of atelicity and the formal semantics of tense.
